GNMT, Google's Translation System

- ◆ 2016년 알파고와 함께 한참 화제가 된 구글의 신경망 기반 기계번역, GNMT
→ RNN을 이용하여 만든 서비스
- ◆ 지속적인 학습으로 빠르게 성능을 개선하여, 몇몇 언어에서는 인간에 가까운 수준에 도달

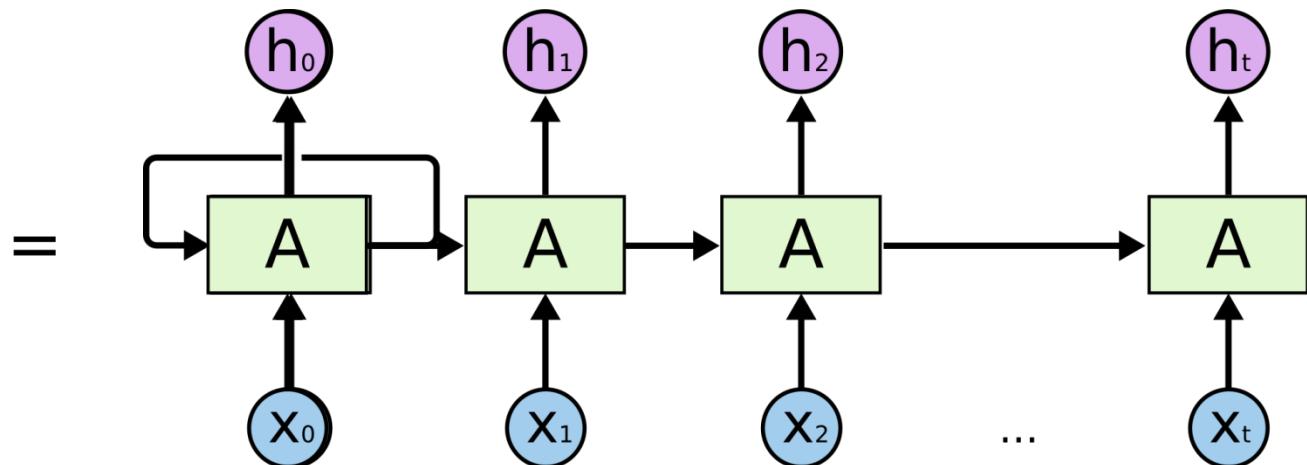

[구글 기계번역 성능 그래프, 출처: <https://goo.gl/jRlrL4>]

RNN (Recurrent Neural Network)

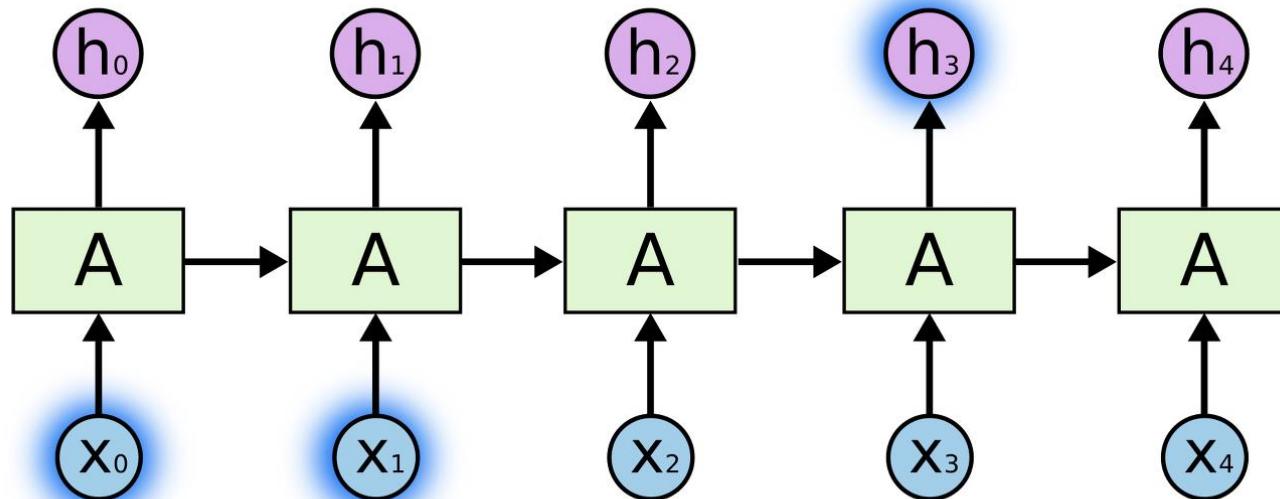

- ◆ Deep Learning 알고리즘 중 순차적인 데이터를 학습하여 Classification / Prediction 수행
- ◆ 기존의 DNN(Deep Neural Network)의 경우 각 Layer마다 parameter 들이 독립적이었으나, RNN은 이를 공유
- ◆ 현재의 출력 결과는 이전 time step의 결과에 영향을 받으며, hidden layer는 일종의 메모리 역할을 하게 됨

Long-Term Dependency Problem

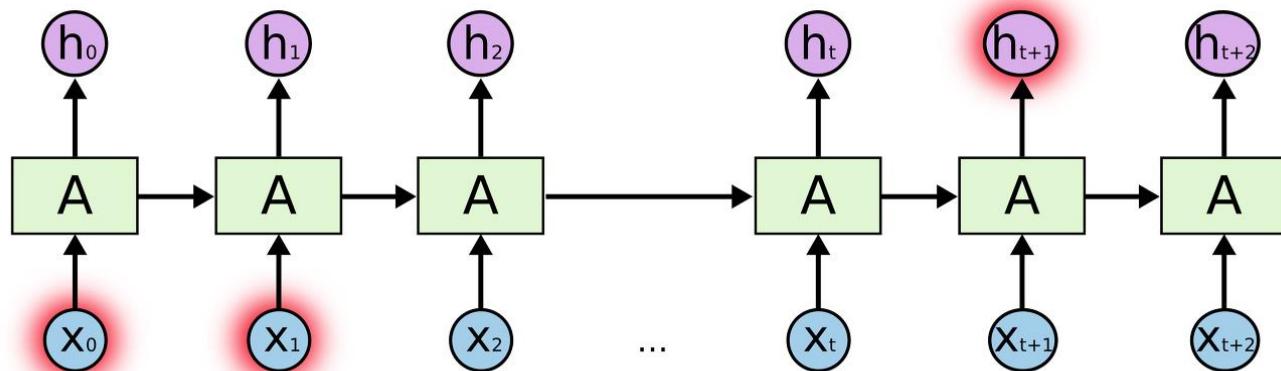

- ◆ RNN의 장점은 이전의 정보를 현재의 문제 해결에 활용할 수 있다는 점이다.
- ◆ 제공된 데이터와 배워야 할 정보의 입력 위치 차이(Gap)가 크지 않다면, RNN은 과거의 데이터를 기반으로 학습을 할 수 있다.
- ◆ 하지만, 더 많은 문맥이 필요할 때가 있다.
Eg. "I grew up in France. I speak fluent OOOOOO." → 마지막 단어 **French** 를 예측!

Long-Term Dependency Problem

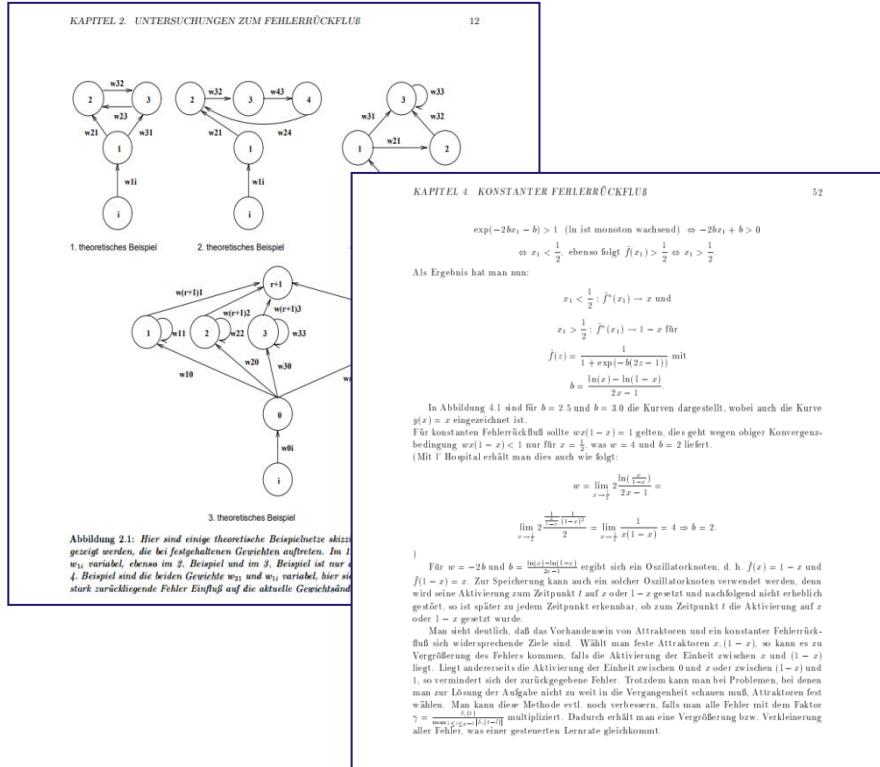

- ◆ 최근 정보를 기반으로 예측 모델은 다음 단어가 아마도 언어의 한 종류라고 예측한다.
- ◆ 실제 “I grew up in France” 는 표현과 “I speak fluent OOOOOO.” 라는 표현의 위치가 멀어지는 문제는 아주 빈번하게 발생한다.
- ◆ 불행히도, 이런 문장표현의 순서상 갭이 커질수록, RNN은 두 정보의 문맥을 연결하기 힘들다.
→ 이러한 **장기의존성 문제**를 풀 수 있도록 신중하게 파라미터를 선택 !?!

Long-Term Dependency Problem

◆ 슬프게도 실제적으로 RNN은 이러한 문맥을 배울 수 없다는 것이 밝혀졌다.

Abstract

Long-term error information is often lost in recurrent neural networks via recurrent backpropagation takes a very long time, mostly due to bifurcations, decaying error back flow. We briefly review Hochreiter's (1991) analysis of this problem, then address it by introducing a novel, efficient, gradient-based method called "Long Short-Term Memory" (LSTM). Truncating the gradient where it does not do harm, LSTM can learn to bridge minimal time lags in excess of 1000 discrete time steps. We compare these results with those of other recurrent models within special units. Multiplicative gate units learn to open and close access to the constant error flow. LSTM is local in space and time, has computational complexity per time step and weight $O(1)$. Our experiments include data sets of handwritten digits and speech digits, and binary pattern representations. In comparison with RTRL, BPPTT, Recurrent Cascade-Correlation, Elman nets, and Neural Sequence Chaining, LSTM also learns to move many successful runs, runs much faster. LSTM also solves complex, artificial long time lag tasks that have never been solved by previous recurrent network algorithms.

1 INTRODUCTION

Recurrent networks can in principle use their feedback connections to store representations of recent input events in form of activations ("short-term memory"), as opposed to "long-term memory" embodied by slowly changing weights. This is potentially significant for many applications, including speech processing, non-Markovian control, and music composition (e.g., Mozer 1994). The main problem is that recurrent networks need to learn to store information that they take too much time or do not work well at all, especially when minimal time lags between inputs and corresponding teacher signals are long. Although theoretically fascinating, existing methods do not provide clear practical advantages over, say, backpropagation in feedforward nets with limited time width. This paper will show that the introduction of a new type of recurrent unit, the "Cellular Unit", can solve long time lag tasks, a preliminary analysis of them, or does not work at all (see Experiments 3).

The problem. With conventional "Back-Propagation Through Time" (BPPTT, e.g., Williams and Zipser 1989, Werbos 1988) or "Real-Time Recurrent Learning" (RTRL, e.g., Robinson and Fallside 1987), signal gradients in time tend to either (1) blow up or (2) vanish, the vanishing evolution of the backpropagated error exponentially depends on the magnitude of the weights (Hochreiter 1991). Case (1) may lead to exploding weights, while in case (2) learning to bridge long time lags takes a prohibitive number of steps, or does not work at all (see Experiments 3).

Key remedy. This paper presents "Long Short-Term Memory" (LSTM), a novel recurrent network architecture that combines an appropriate gradient-based learning algorithm. LSTM is designed to overcome these error backflow problems. It can learn to bridge time intervals in excess of 1000 steps even in case of noisy, incompressible input sequences, without loss of short time lag capabilities. This is achieved by an efficient, gradient-based algorithm for an architecture

where

$$\text{net}_{\text{out},i}(t) = \sum_u w_{\text{out},iu} y^u(t-1),$$

and

$$\text{net}_{\text{in},i}(t) = \sum_u w_{\text{in},iu} y^u(t-1).$$

We also have

$$\text{net}_{\text{c}}(t) = \sum_u w_{\text{c},iu} y^u(t-1).$$

The summation indices a may stand for input units, gate units, memory cells, or even conventional hidden units if there are any (see also paragraph on "network topology" below). All these different types of units may convey useful information about the current state of the net. For instance, an input gate (output gate) may use inputs from other memory cells to decide whether to store (access) certain information in its memory cell. There may even be recurrent self-connections like $w_{\text{c},i}$, that is, up to the next time step define the network topology. See Figure 1 for an example.

At time t , c_i 's output $y^i(t)$ is computed as

$$y^i(t) = g^{\text{act}}(t) h(\sigma_c(t)),$$

where the "internal state" $\sigma_c(t)$ is

$$\sigma_c(t) = 0, \sigma_{c,j}(t) = \sigma_c(t-1) + y^{\text{in},j}(t) g^{\text{in}}(t) \text{ net}_{\text{in},j}(t) \quad \text{for } t > 0.$$

The differentiable function g squashes net_{c} ; the differentiable function h scales memory cell outputs computed from the internal state σ_c :

Figure 1: Definition of memory cell c_i (the box) and its gate units $\text{net}_{\text{in},i}$, $\text{net}_{\text{out},i}$. The self-recurrent connection $(\text{net}_{\text{c}}, \text{net}_{\text{c}})$ with weight $w_{\text{c},i}$ indicates feedback with a delay of 1 time step. It builds the basis of the "constant error arrows" (CEC). The gate units open and close access to CEC. See text and appendix A.1 for details.

Figure 2: Example of a net with 8 input units, 4 output units, and 9 memory cells.

The diagram shows a network structure with 8 input units, 4 output units, and 9 memory cells. Each memory cell is represented by a box labeled 'cell 1' or 'cell 2' with 'block 1' or 'block 2'. The connections between units are shown with arrows, illustrating dense connectivity and various connection types (e.g., bidirectional, self-loops, and specific connections between units).

Figure 3: Transition diagram for the embedded Reber grammar.

This is a directed graph representing the transition rules of the Reber grammar. Nodes are labeled with symbols from the grammar: S, T, E, B, P, V, X, and T. Edges represent transitions between states, such as S → T, T → E, E → B, B → P, P → V, V → T, and T → S. Some edges are labeled with symbols like 'P' or 'B'.

Figure 4: Transition diagram for the embedded Reber grammar.

This diagram shows a more complex transition graph for the Reber grammar. It includes additional nodes and edges compared to Figure 3, representing a larger state space. The nodes are labeled with symbols from the grammar, and the edges show the sequence of transitions required to generate strings according to the grammar rules.

Figure 5: Detailed experimental conditions for Experiments 1–6.

This table provides detailed experimental conditions for six different experiments. It includes columns for task type, input sequence length, time lag, noise level, and specific parameters for each experiment (e.g., number of units, initial bias values, etc.).

minimal time lags would make this almost impossible. The more interesting tasks in our paper, however, are those that RTRL, BPPTT, etc. cannot solve at all.

- Experiment 2 focuses on noise-free and noisy sequences involving numerous input symbols distract from the few important ones. The most difficult task (Task 2) involves hundreds of distractor symbols at random positions, and minimal time lags of 1000 steps. LSTM solves while BPPT and RTRL already fail in case of 10-step minimal time lags (see also, e.g., Hochreiter and Schmidhuber 1992). For the noise-free case, RTRL and BPPT failed in the remaining, more complex experiments, all of which involve much longer time lags.
- Experiment 3 addresses long time lag problems with noise and signal on the same input line. Experiments 3/3 focus on Beagle et al.'s 1991 "2-sequence problem". Because this problem actually can be solved quickly by random weight guessing, we also include a far more difficult 2-sequence problem (3c) which requires to learn real-valued, conditional expectations of noisy targets, given the inputs.

- Experiment 4 addresses long time lag problems with noise and signal on the same input line, but using sparse, real values for very long time periods. Relevant input signals can occur at quite different positions in input sequences. Again minimal time lags involve hundreds of steps. Similar tasks never have been solved by other recurrent net algorithms.
- Experiment 6 involves tasks of a different complex type that also has not been solved by other recurrent net algorithms. Again, relevant input signals can occur at quite different positions in input sequences. The experiment shows that LSTM can extract information conveyed by the temporal order of widely-spread input units.

Subsection 5.7 will provide a detailed summary of experimental conditions in two tables for reference.

5.1 EXPERIMENT 1: EMBEDDED REBER GRAMMAR

Task. Our first task is to learn the "embedded Reber grammar", e.g., Smith and Zipser (1989), Clevermann et al. (1989), and Fallside (1991). Since it allows for training sequences with short time lags (of as few as 9 steps), it is not a long time lag problem. We include it for two reasons: (1) it is a long-standing benchmark used by many authors — we wanted to have at least one experiment where RTRL and BPPTT do not fail completely, and (2) it shows nicely how output gates can be beneficial.

Figure 4: Transition diagram for the embedded Reber grammar. Each box represents a copy of the Reber grammar (see Figure 3).

Starting at the leftmost node of the directed graph in Figure 4, symbol strings are generated sequentially (beginning with the empty string) by following edges — and appending the associated

Vanishing Gradient

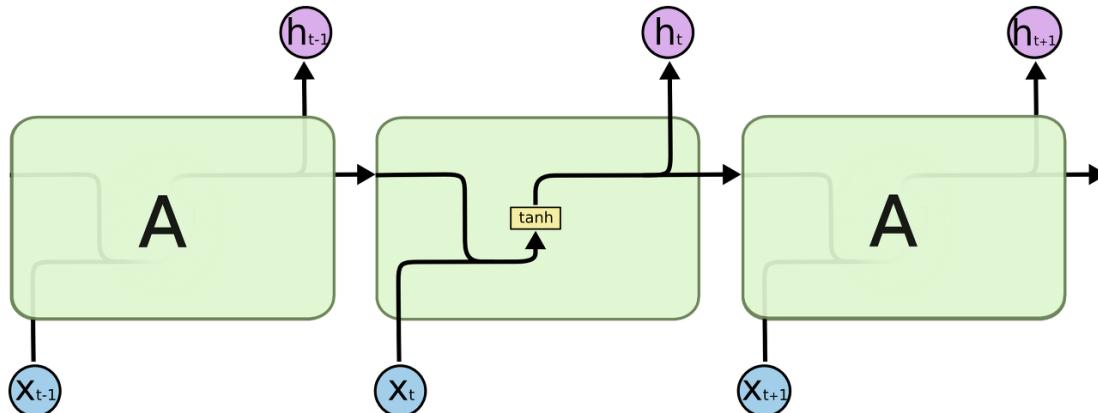

- ◆ 긴 기간의 의미를 파악하지 못하고 짧은 기간 만이 유의미해지므로 기억력이 좋지 못한 모델이 된다.
- ◆ 이를 해결하지 등장한 것이 **LSTM(Long Short Term Memory Units)**이다.

LSTM, Long Short Term Memory

- ◆ LSTM은 장기 의존성 문제를 해결하기 위해 명시적으로 디자인되었다.
- ◆ 오랜 기간 동안 정보를 기억하는 일은 LSTM에 있어 특별한 작업 없이도 기본적으로 동작
- ◆ 모든 RNN은 **뉴럴 네트워크의 반복되는 체인으로 구성**되어 있다.
→ 표준 RNN에서 반복되는 모듈은 아주 단순한 구조를 가지고 있다.
eg. 단일 tanh 레이어

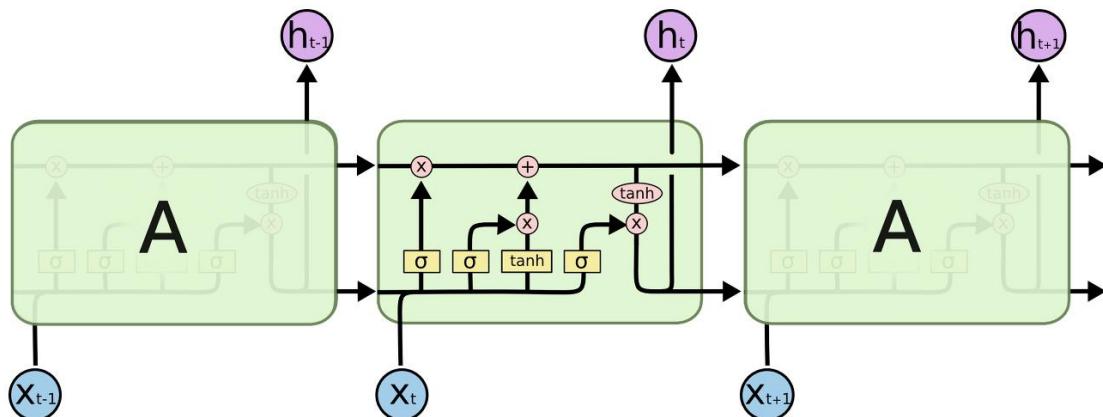

[싱글 레이어를 가지고 있는 반복되는 표준 RNN 모듈]

LSTM, Long Short Term Memory

- ◆ LSTM도 마찬가지로 체인구조를 가지고 있다. 하지만, 반복되는 모듈은 다른 구조이다.
- ◆ LSTM은 단일 뉴럴 네트워크 레이어를 가지는 것 대신에
→ **4개의 상호작용 가능한 특별한 방식의 구조**를 가지고 있다.
- ◆ 다이어그램에서 각 라인은 온전한 vector를 포함한다. 각 출력값은 다른 노드의 입력값.

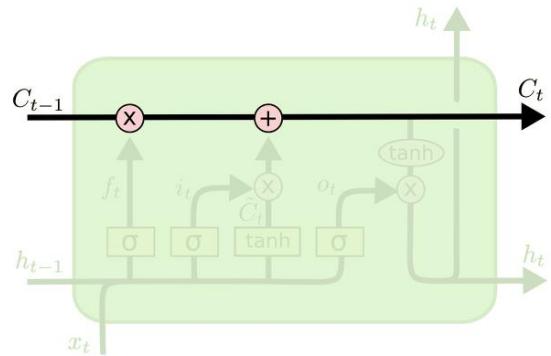

[LSTM에 들어있는 4개의 상호작용하는 레이어가 있는 반복되는 모듈]

LSTMs의 핵심 아이디어

- ◆ LSTM의 핵심은 셀 스테이트(The Cell State)이다. 다이어그램 상단에 있는 수평선이다.
- ◆ 셀 스테이트는 하나의 컨베이어 벨트와 같다.
 - 이것은 아주 마이너한 선형 연산을 거치고 전체 체인을 관통한다.

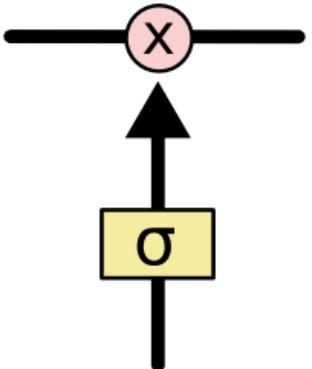

[싱글 레이어를 가지고 있는 반복되는 표준 RNN 모듈]

LSTMs의 핵심 아이디어

- ◆ LSTM은 셀 스테이트에 신중하게 정제된 구조를 가진 게이트(gate)라는 요소를 활용하여 정보를 더하거나 제거하는 기능을 가지고 있다.
- ◆ 게이트(Gates)들은 선택적으로 정보들이 흘러들어갈 수 있도록 만드는 장치이다.
→ 이들은 시그모이드 뉴럴넷(Sigmoid Neural Net Layer)와 점단위 곱하기 연산으로 이루어짐
- ◆ 시그모이드 레이어는 0 혹은 1의 값을 출력한다.
→ 0이라는 값을 가지면, 해당 구성요소가 미래의 결과에 아무 영향도 주지 않도록 만든다.
→ 반면 1이라는 값은 해당 구성요소가 미래 예측결과에 영향을 주도록 데이터가 흘러가게 만든다.

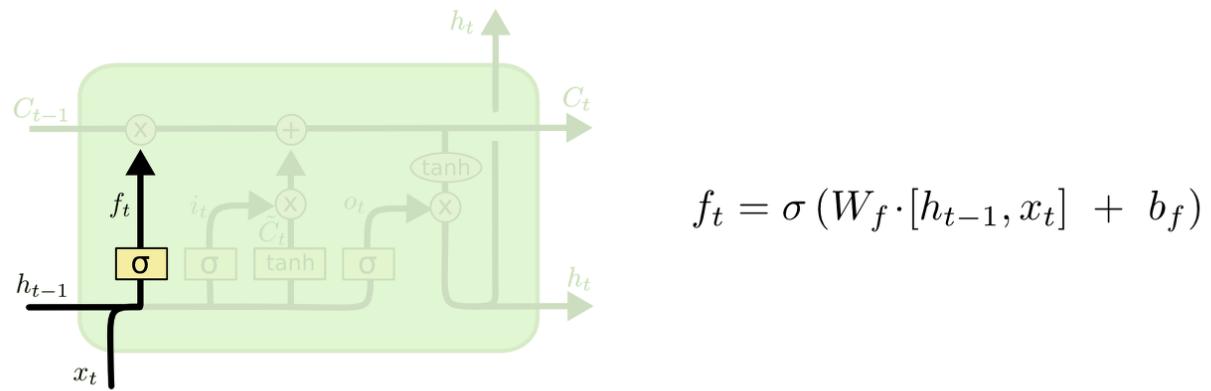

[시그모이드 레이어]

LSTM, STEP 1

- ◆ LSTM 첫번째 스텝 : 셀 스테이트에서 어떤 정보를 버릴지 선택하는 과정이다.

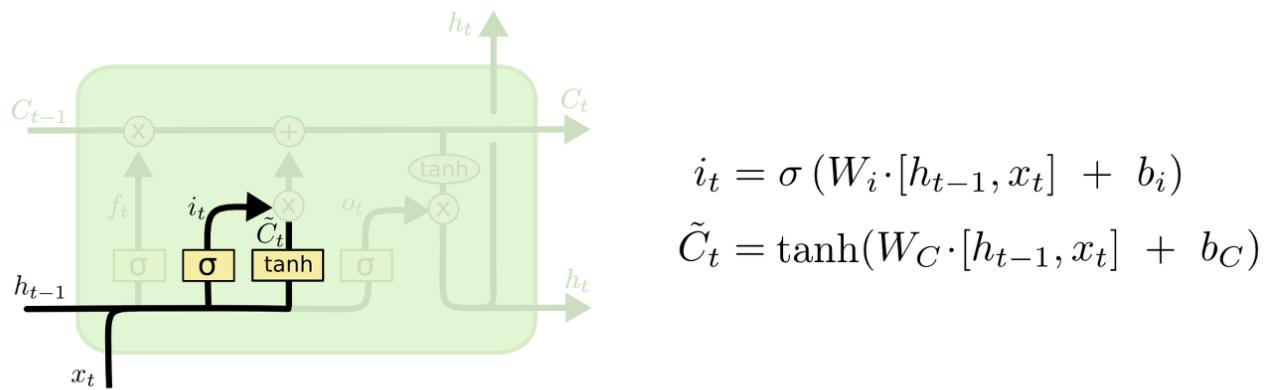

[LSTM – STEP1]

LSTM, STEP 2

- ◆ LSTM 두번째 스텝 : 새로운 정보가 셀 스테이트에 저장될지를 결정하는 단계이다.

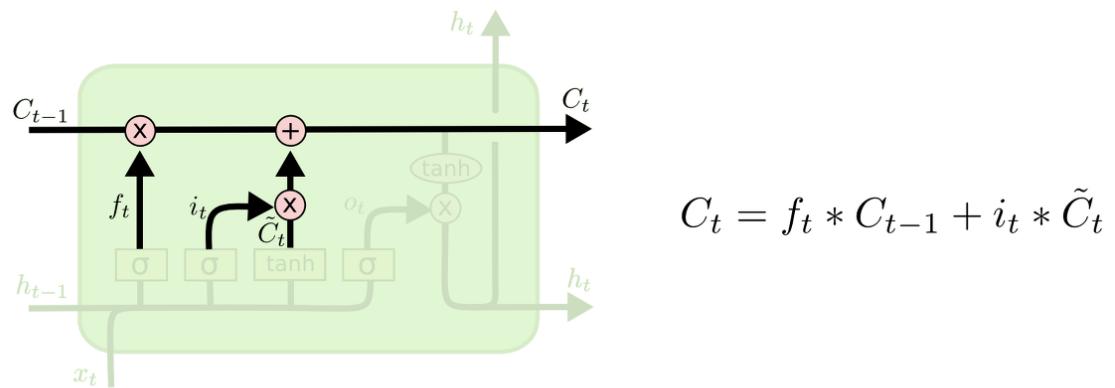

[LSTM – STEP2]

LSTM, STEP 3

- ◆ LSTM 세번째 스텝 : 오래된 셀 스테이트(C_{t-1})를 새로운 스테이트인(C_t)로 업데이트 할 시간이다.
- ◆ 전 단계에서 무엇을 할지 이미 결정했다. 그래서, 이 연산을 수행하기만 하면 된다.

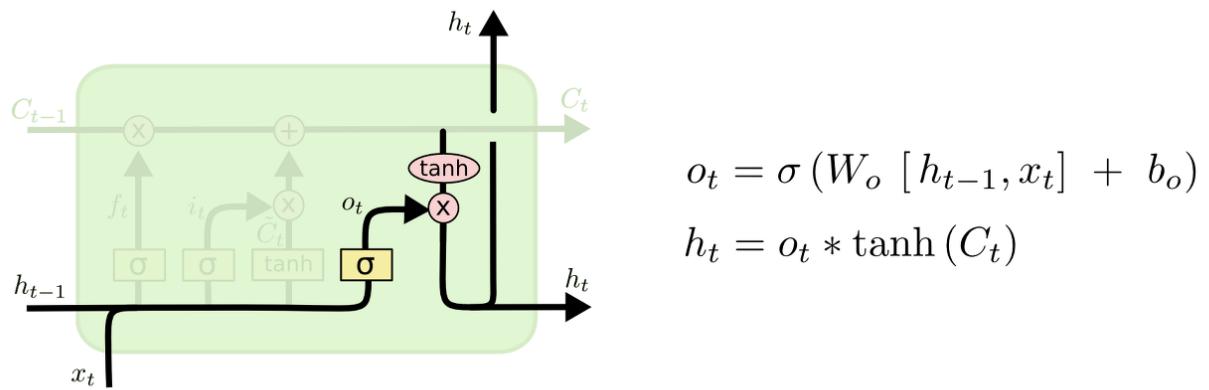

[LSTM – STEP3]

LSTM, STEP 4

- ◆ LSTM 네번째 스텝 : 어떤 출력값을 출력할지 결정해야 한다.
- ◆ 이 출력값은 우리의 세 스테이트(cell state) 하지만 필터링 된 버전이다.

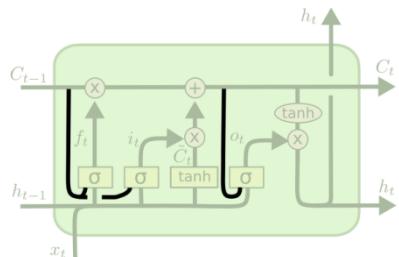

[LSTM – STEP4]

LSTM의 변칙 패턴

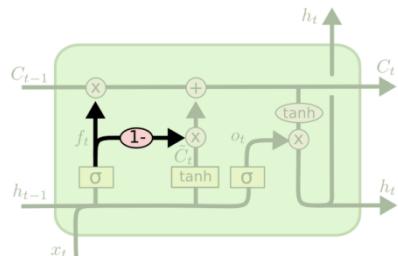

- ◆ 모든 LSTM 이 위와 같은 동일한 구조를 갖고 있지는 않다.
- ◆ 사실 LSTM 을 구현한 모든 논문들은 서로서로 약간 다른 구현체 버전을 가지고 있다.
- ◆ 그 차이들은 사실 그리 중요하지 않다.

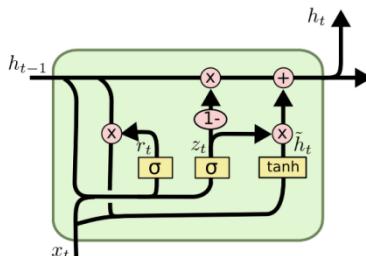

$$f_t = \sigma(W_f \cdot [C_{t-1}, h_{t-1}, x_t] + b_f)$$
$$i_t = \sigma(W_i \cdot [C_{t-1}, h_{t-1}, x_t] + b_i)$$
$$o_t = \sigma(W_o \cdot [C_t, h_{t-1}, x_t] + b_o)$$

[LSTM - 변칙1]

$$C_t = f_t * C_{t-1} + (1 - f_t) * \tilde{C}_t$$

[LSTM - 변칙2]

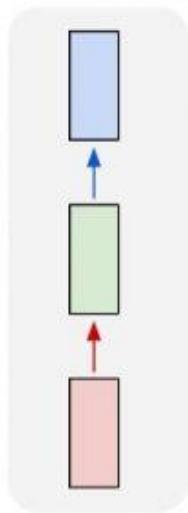

$$z_t = \sigma(W_z \cdot [h_{t-1}, x_t])$$
$$r_t = \sigma(W_r \cdot [h_{t-1}, x_t])$$
$$\tilde{h}_t = \tanh(W \cdot [r_t * h_{t-1}, x_t])$$
$$h_t = (1 - z_t) * h_{t-1} + z_t * \tilde{h}_t$$

[LSTM - 변칙3]

Video classification on frame level

RNN Architecture

Each rectangle is a vector and arrows represent functions (e.g. matrix multiply). Input vectors are in red, output vectors are in blue and green vectors hold the RNN's state (more on this soon). From left to right: (1) Vanilla mode of processing without RNN, from fixed-sized input to fixed-sized output (e.g. image classification). (2) Sequence output (e.g. image captioning takes an image and outputs a sentence of words). (3) Sequence input (e.g. sentiment analysis where a given sentence is classified as expressing positive or negative sentiment). (4) Sequence input and sequence output (e.g. Machine Translation: an RNN reads a sentence in English and then outputs a sentence in French). (5) Synced sequence input and output (e.g. video classification where we wish to label each frame of the video). Notice that in every case are no pre-specified constraints on the lengths of sequences because the recurrent transformation (green) is fixed and can be applied as many times as we like.

RNN의 응용

Text Generation

이전 단어들을 보고 다음 단어가 나올 확률을 예측하는 언어 모델을 기반으로 텍스트를 생성하는 **generative model**을 만들 수 있음

Language Translation

Word sequence를 입력으로 사용하여 번역할 언어의 word sequence로 출력

Speech Recognition

Acoustic signal을 입력으로 받아 phonetic segment의 sequence 또는 probability distribution을 추측

Summary

- ◆ 일찍이 RNN을 활용하여 엄청난 성과를 거두고 있다는 사실을 언급했다.
- ◆ 핵심적으로 모든 이러한 것들은 LSTM을 활용한 결과였다.
- ◆ LSTM은 거의 모든 영역에서 다른 RNN 알고리즘에 비해 탁월한 성능을 보여주고 있다.

Practice

2. RNN Sentence Sequence

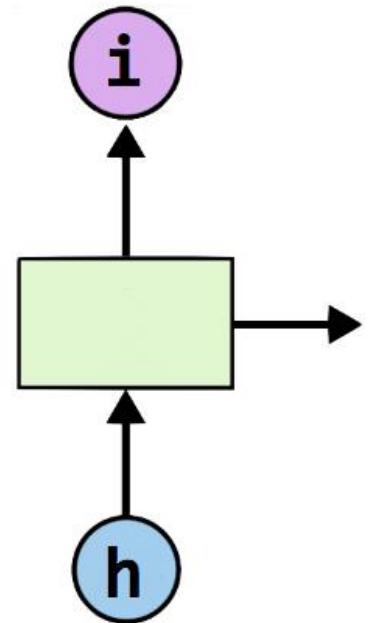

Teach RNN 'hihello'

One-hot encoding

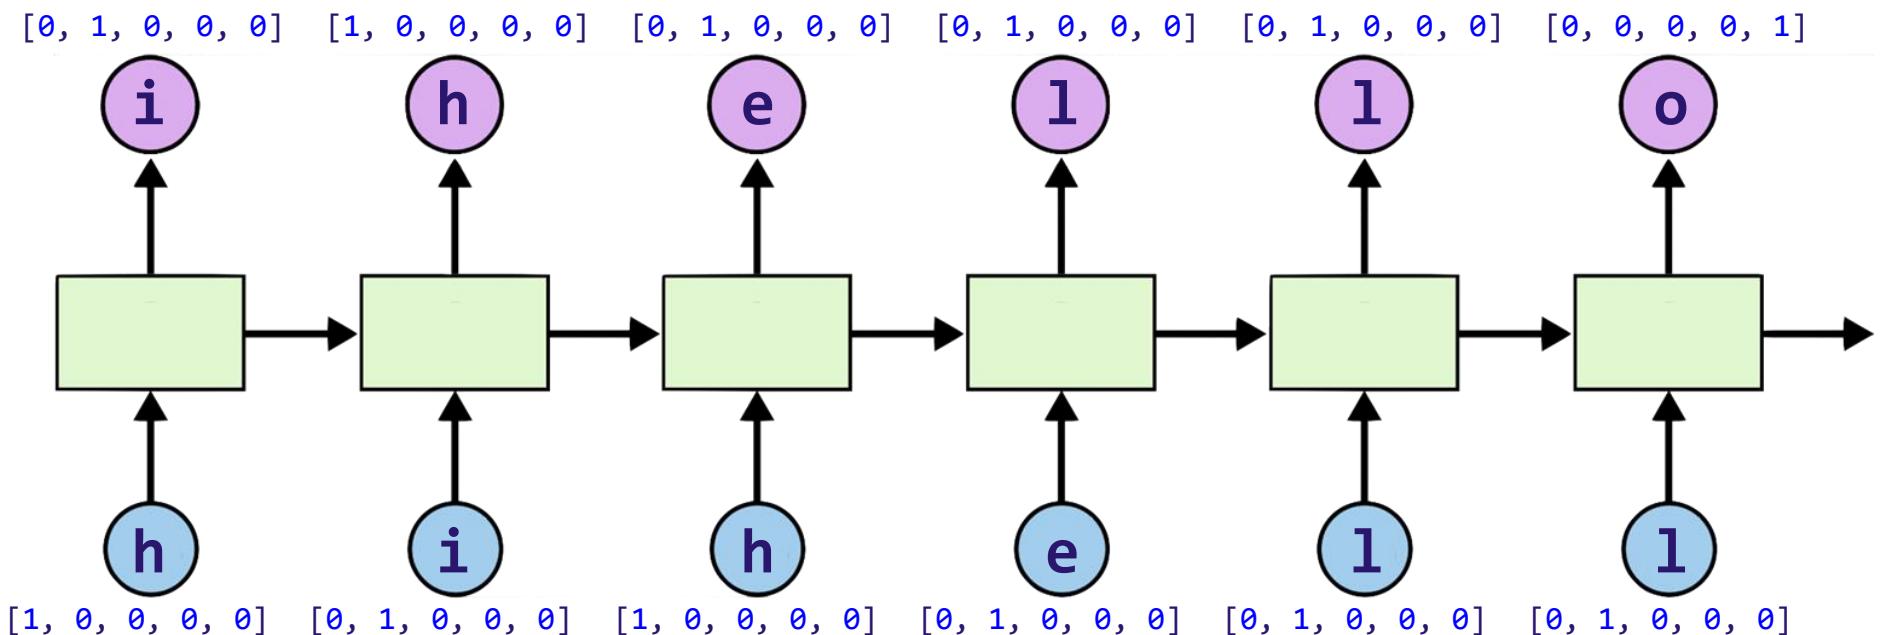

```
[1, 0, 0, 0, 0],    # h 0  
[0, 1, 0, 0, 0],    # i 1  
[0, 0, 1, 0, 0],    # e 2  
[0, 0, 0, 1, 0],    # l 3  
[0, 0, 0, 0, 1],    # o 4
```

Teach RNN 'nihello'

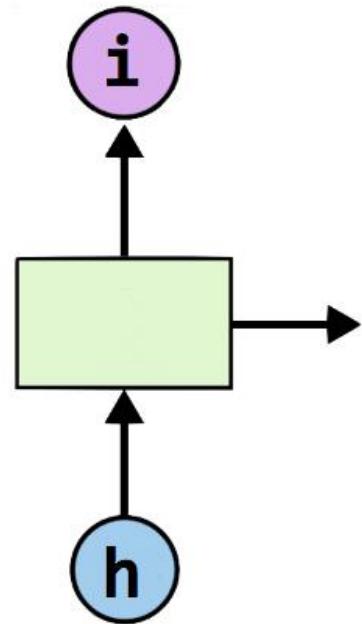

```
[1, 0, 0, 0, 0], # h 0  
[0, 1, 0, 0, 0], # i 1  
[0, 0, 1, 0, 0], # e 2  
[0, 0, 0, 1, 0], # l 3  
[0, 0, 0, 0, 1], # o 4
```

Creating RNN Cell

```
# RNN model  
rnn_cell = rnn_cell.BasicRNNCell(rnn_size)
```

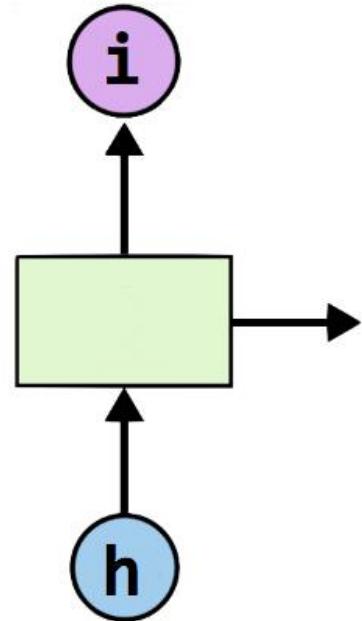

Creating RNN Cell

```
# RNN model  
rnn_cell = rnn_cell.BasicRNNCell(rnn_size)
```

```
rnn_cell = rnn_cell.BasicLSTMCell(rnn_size)  
rnn_cell = rnn_cell.GRUCell(rnn_size)
```

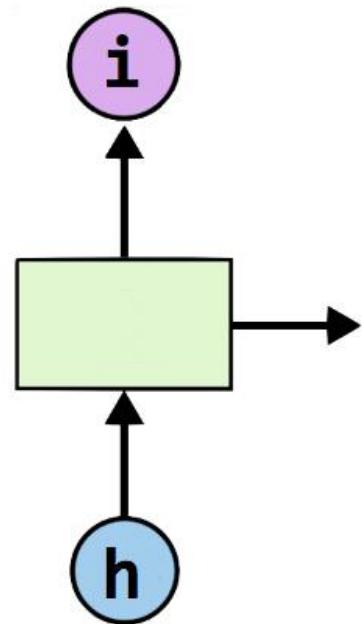

Execute RNN

```
# RNN model
rnn_cell = rnn_cell.BasicRNNCell(rnn_size) ①

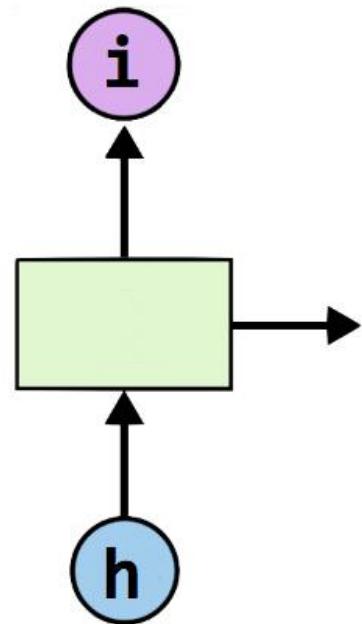

outputs, _states = tf.nn.dynamic_rnn(
    rnn_cell,
    x,
    ② initial_state=initial_state,
    dtype=tf.float32)
```

RNN Parameters

```
hidden_size = 5      # output from the LSTM  
input_dim = 5        # one-hot size  
batch_size = 1       # one sentence  
sequence_length = 6  # |ihello| == 6
```

Data Creation

```
idx2char = ['h', 'i', 'e', 'l', 'o'] # h=0, i=1, e=2, l=3, o=4
x_data = [[0, 1, 0, 2, 3, 3]] # hiheLL
x_one_hot = [[[1, 0, 0, 0, 0], # h 0
              [0, 1, 0, 0, 0], # i 1
              [1, 0, 0, 0, 0], # h 0
              [0, 0, 1, 0, 0], # e 2
              [0, 0, 0, 1, 0], # l 3
              [0, 0, 0, 1, 0]]] # l 3

y_data = [[1, 0, 2, 3, 3, 4]] # ihello

                     [batch_size, seq_length, num_classes])
```

Loss

```
# reshape out for sequence_loss
outputs = tf.reshape(outputs,
                      [batch_size, seq_length, num_classes])
# ALL weights are 1 (equal weights)
weights = tf.ones([batch_size, seq_length])

sequence_loss = tf.contrib.seq2seq.sequence_loss(
    logits=outputs, targets=Y, weights=weights)
mean_loss = tf.reduce_mean(sequence_loss)

train_op =
    tf.train.AdamOptimizer(learning_rate=0.1).minimize(mean_loss)
```

Training and print results

```
sess = tf.Session()
sess.run(tf.global_variables_initializer())

for i in range(500):
    _, l, results = sess.run(
        [train_op, mean_loss, outputs],
        feed_dict={X: dataX, Y: dataY})

for j, result in enumerate(results):
    index = np.argmax(result, axis=1)
    print(i, j, ''.join([char_set[t] for t in index]), l)
```

```
0 167 tttttttttt 3.23111
0 168 tttttttttt 3.23111
0 169 tttttttttt 3.23111
...
499 167 oof the se 0.229306
499 168 tf the sea 0.229306
499 169 n the sea. 0.229306
```

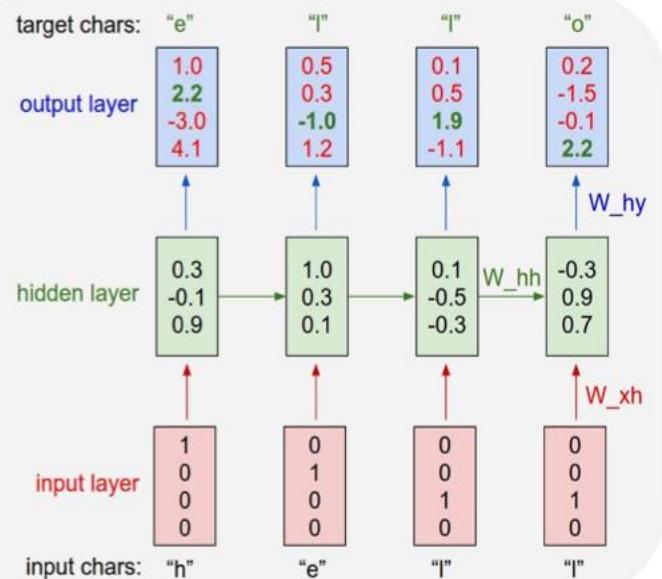

Training and print results

```
# Let's print the last char of each result to check it works
results = sess.run(outputs, feed_dict={X: dataX})
for j, result in enumerate(results):
    index = np.argmax(result, axis=1)
    if j is 0: # print all for the first result to make a
sentence
        print(''.join([char_set[t] for t in index]), end='')
    else:
        print(char_set[index[-1]], end='')
```

g you want to build a ship, don't drum up people together to collect wood and don't assign them tasks and work, but rather teach them to long for the endless immensity of the sea.

Char-RNN

Shakespeare

It looks like we can learn to spell English words. But how about if there is more structure and style in the data? To examine this I downloaded all the works of Shakespeare and concatenated them into a single (4.4MB) file. We can now afford to train a larger network, in this case lets try a 3-layer RNN with 512 hidden nodes on each layer. After we train the network for a few hours we obtain samples such as:

PANDARUS:

Alas, I think he shall be come approached and the day
When little strain would be attain'd into being never fed,
And who is but a chain and subjects of his death,
I should not sleep.

Second Senator:

They are away this miseries, produced upon my soul,
Breaking and strongly should be buried, when I perish
The earth and thoughts of many states.

DUKE VINCENTIO:

Well, your wit is in the care of side and that.

Second Lord:

They would be ruled after this chamber, and
my fair nues begun out of the fact, to be conveyed,
Whose noble souls I'll have the heart of the wars.

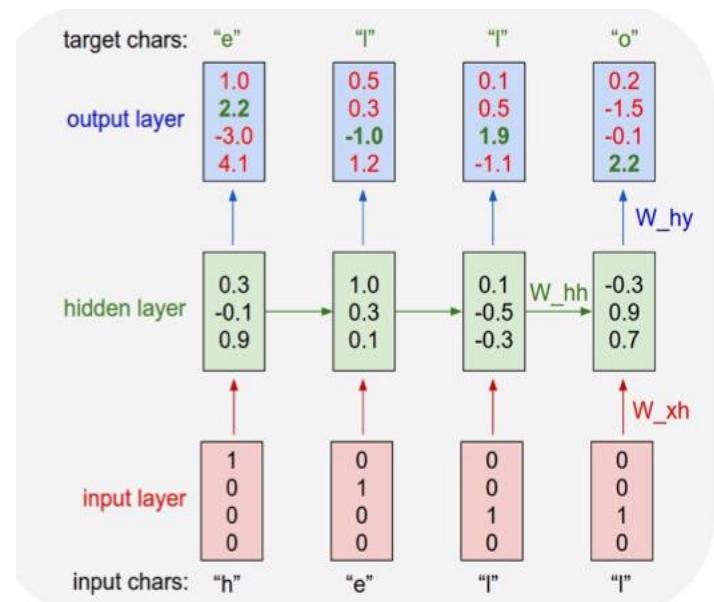

Clown:

Come, sir, I will make did behold your worship.

VIOLA:

I'll drink it.

Char-RNN

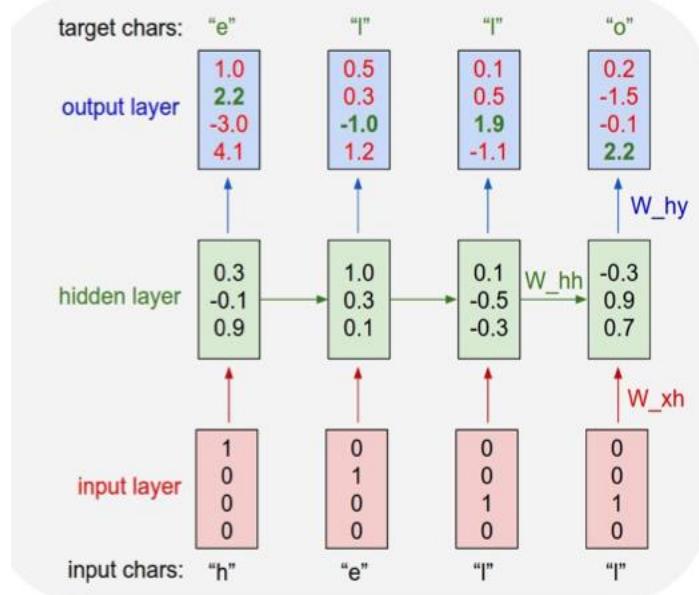

Linux Source Code

I wanted to push structured data to its limit, so for the final challenge I decided to use code. In particular, I took all the source and header files found in the [Linux repo on Github](#), concatenated all of them in a single giant file (474MB of C code) (I was originally going to train only on the kernel but that by itself is only ~16MB). Then I trained several as-large-as-fits-on-my-GPU 3-layer LSTMs over a period of a few days. These models have about 10 million parameters, which is still on the lower end for RNN models. The results are superfun:

```
/*
 * Increment the size file of the new incorrect UI_FILTER group information
 * of the size generatively.
 */
static int indicate_policy(void)
{
    int error;
    if (fd == MARN_EPT) {
        /*
         * The kernel blank will coeld it to userspace.
         */
        if (ss->segment < mem_total)
            unblock_graph_and_set_blocked();
        else
            ret = 1;

# optimizer
optimizer = tf.train.GradientDescentOptimizer(0.01)
train = optimizer.minimize(loss)
```

Training and Results

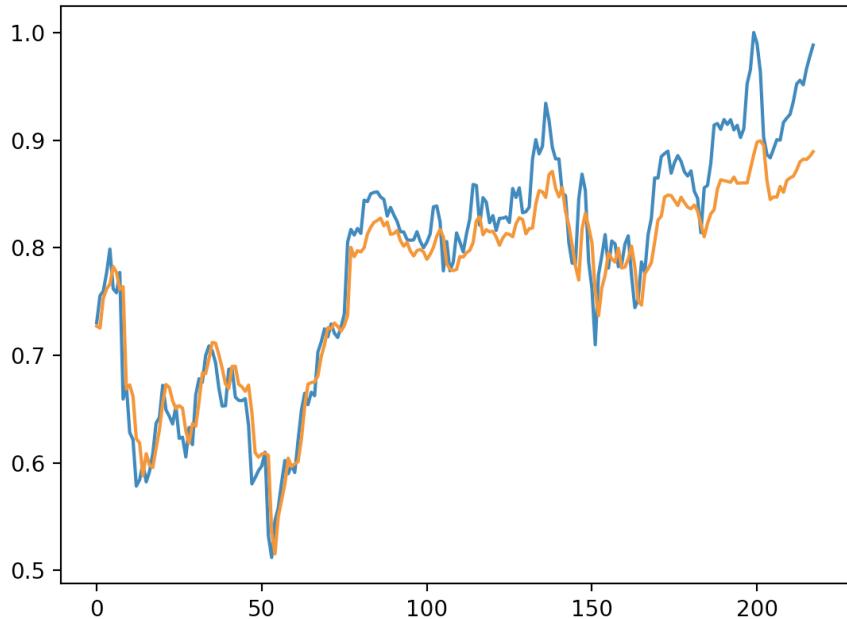

```
sess = tf.Session()
sess.run(tf.global_variables_initializer())

for i in range(1000):
    _, l = sess.run([train, loss],
                   feed_dict={X: trainX, Y: trainY})
    print(i, l)

testPredict = sess.run(Y_pred, feed_dict={X: testX})

import matplotlib.pyplot as plt
plt.plot(testY)
plt.plot(testPredict)
plt.show()
```

Exercise

- ❖ Implement stock prediction using linear regression only
- ❖ Improve results using more features such as keywords and/or sentiments in top news

Other RNN Applications

- ❖ Language Modeling
- ❖ Speech Recognition
- ❖ Machine Translation
- ❖ Conversation Modeling/Question Answering
- ❖ Image/Video Captioning
- ❖ Image/Music/Dance Generation
